

Common Mistakes and Misconceptions in Chemistry: How Not to Be an Easy Target For Exam-Writers Who are Out to Stump You

New Topics To Chemistry V
Ksp

1. Writing the wrong ionic equation for something like $\mathbf{C a F}_{2(s)}$
$\mathrm{CaF}_{2}$ forms when Ca gives its two valence electrons to different F atoms, each of which can only accommodate 1 more electron. This creates $1 \mathrm{Ca}^{2+}$ ion and $\boldsymbol{t W O}$ separate $\mathrm{F}^{-}$ions. So the equation becomes:

$$
\mathbf{C a F}_{2(\mathrm{~s})} \rightleftharpoons \mathrm{Ca}^{2+}+2 \mathrm{~F}^{-}
$$

2. Placing solubility in the wrong place in ice chart and writing the wrong equilibrium expression.

|  | $\mathrm{CaF}_{2(\mathrm{~s}}$ | $\rightleftharpoons \mathrm{Ca}^{2+}$ | $+2 \mathrm{~F}^{-}$ |
| :---: | :---: | :---: | :---: |
| I |  | 0 | 0 |
| C | Solubility goes here: example $2.05 \times 10^{-4} \mathrm{~mol} / \mathrm{L}$ | Stoichiometry applies $2.05 \times 10^{-4} \mathrm{~mol} / \mathrm{L}$ | Stoichiometry applies 2:1 <br> 4.10 $\times 10^{-4} \mathrm{~mol} / \mathrm{L}$ |
| E |  | $2.05 \times 10^{-4} \mathrm{~mol} / \mathrm{L}$ | 4.10 X $10{ }^{-4} \mathrm{~mol} / \mathrm{L}$ |

$K s p=\left[2.05 \times 10^{-4} \mathrm{~mol} / \mathrm{L}\right]\left[4.10 \times 10^{-4} \mathrm{~mol} / \mathrm{L}\right]^{2}=3.45 \times 10^{-11}$
Notice the solid does not go into the denominator; it's a constant!

## Estimating $\Delta H$ From Bond Energies

3. Forgetting that the energy invested to break bonds is $\Delta \mathrm{H}_{\mathrm{bb}}=(+)$

And that the energy released when bonds are formed is $\Delta \mathrm{H}_{\mathrm{bf}}=(-)$. The enthalpy is then obtained by adding the above two values.

## Example:

Estimate the $\Delta \mathrm{H}$ per mole of $\mathrm{H}_{2}$ for the following reaction: $\mathrm{H}_{2}+$ $\mathrm{Br}_{2} \rightarrow 2 \mathrm{HBr}$

|  |  | $\mathrm{H}-\mathrm{Br}$ |
| :---: | :---: | :---: |
| $\mathrm{H}-\mathrm{H}$ <br> hydrogen | $\mathrm{Br}-\mathrm{Br}$ bromine | hydrogen bromide |

progress

| $\Delta \mathrm{H}_{\mathrm{bb}}$ | $\Delta \mathrm{H}_{\mathrm{bf}}$ | $\Delta \mathrm{H}=\Delta \mathrm{H}_{\mathrm{bb}}+\Delta \mathrm{H}_{\mathrm{bf}}$ |
| :---: | :--- | :--- |
| $436 \mathrm{~kJ}+193 \mathrm{~kJ}=629 \mathrm{~kJ}$ | $-366 \mathrm{~kJ} * 2=-732 \mathrm{~kJ}$ | $-732 \mathrm{~kJ}+629 \mathrm{~kJ}=$ |
|  |  | -103 kJ |
|  |  |  |

Table of Bond Energies to consult:
Table of Bond Energies to consult:

| Bond | Energy(kJ/mole) | Bond | Energy(kJ/mole) |
| :---: | :---: | :---: | :---: |
| $\mathrm{C}-\mathrm{H}$ | 413 | $\mathrm{C} \equiv \mathrm{C}$ | 839 |
| $\mathrm{H}-\mathrm{H}$ | 436 | $\mathrm{C}-\mathrm{O}$ | 358 |
| $\mathrm{H}-\mathrm{Br}$ | 366 | $\mathrm{C}=\mathrm{O}$ | 745 |
| $\mathrm{Br}-\mathrm{Br}$ | 193 | $\mathrm{C}=\mathrm{C}$ | 607 |
| $\mathrm{O}-\mathrm{H}$ | 460 | $\mathrm{O}=\mathrm{O}$ | 498 |
| $\mathrm{C}--\mathrm{C}$ | 340 |  |  |

## Gases

4. Using $\boldsymbol{n}$ in $P V=n R T$ for $\boldsymbol{a}$ Substance that is Not in the Gaseous State.

Example: If 2.0 moles of $\mathrm{H}_{2} \mathrm{O}_{2}$ liquid decomposed and produced oxygen at 101.3 kPa at what temperature was the gas collected in a 2.0 L vessel?

$$
2 \mathrm{H}_{2} \mathrm{O}_{2(\mathrm{l})} \rightarrow \mathrm{O}_{2(\mathrm{~g})}+2 \mathrm{H}_{2} \mathrm{O}
$$

Solution $\quad$ PV = nRT only works for ideal gases, not for real gases or liquids or solids. So in this case, we cannot use 2.0 as a value for $n$. Instead, we have to consider the stoichiometric relationship between $\mathrm{H}_{2} \mathrm{O}_{2}$ and $\mathrm{O}_{2}$. Since
 the ratio is 2 to 1 , and if 2.0 moles of hydrogen peroxide reacted, only 1.0 mole of oxygen is produced.

$$
\mathbf{T}=\mathbf{P V} /(\mathbf{n R})=\frac{101.3 k P a(2.0 L)}{1.0 \text { mole }\left(\frac{8.31 L k P a}{K \text { mole }}\right)}=24 \mathrm{~K}
$$

## 5. Unit-Butchery $\rightarrow$ Ignoring $R$ 's $k P a L /(K$ mole $)$

Example: $\quad$ What is the total mass of a 250.0 mL flask with a tare weight of 200.00 g if it contains hydrogen gas at $22.5^{\circ} \mathrm{C}$ and at 888 mm of Hg ? Note $101.3 \mathrm{kPa}=760 \mathrm{~mm}$ of Hg

Solution Use the factor label method with the given conversions, and they can throw any gorilla-units at you, and you will not even flinch.
$\mathbf{n}=\mathbf{P V} / \mathbf{R T}=\frac{888 \mathrm{~mm} \mathrm{Hg}\left[\frac{101.3 \mathrm{kPa}}{760 \mathrm{~mm} \mathrm{Hg}}\right](0.250 \mathrm{~L})}{\frac{8.31 \mathrm{LkPa}}{K \text { mole }}(22.5+273.15 \mathrm{~K})}=0.0120439 \ldots$. oles of $\mathrm{H}_{2}$
Now convert to grams and then add the tare weight of the flask:
0.0120439 moles ( 2.00 g of $\mathrm{H}_{2} / \mathrm{mole}$ ) $=0.0241 \mathrm{~g}$

Total mass $=200.02 \mathrm{~g}$ with sig figs $\rightarrow 200 . \mathrm{g}$
6. Confusing an Ideal gas with a Real gas.

Example: Four boxes, each at STP with a volume of 22.4 L contain $\mathrm{Ar}, \mathrm{O}_{2}$, He and HCl . Which is least likely to contain exactly 1.00 moles? Will it contain more than $6.02 \times 10^{23}$ molecules?

Solution $\quad \mathbf{H C l}$ is the gas that will not act as an ideal gas because there will be some intermolecular attractions between the $H$ of one molecule and the Cl of a neighbouring molecule. The attractions will cause one mole of HCl at STP to have a volume that is actually less than 22.4 L . So if we consider a 22.4 L box, it will contain proportionally more HCl molecules.

Not convinced? Let's say that one mole of $\mathbf{H C l}$ at $\mathrm{STP}=22.0 \mathrm{~L}$. Then:
22.4 $\mathrm{L}(1$ mole $\mathrm{HCl} / 22.0 \mathrm{~L})\left(6.02 \times 10^{23}\right.$ molecules $)>6.02 \times 10^{23}$ molecules.

## 7. Applying Charles Law when Pressure is not Constant.

Example: A steel container containing 20.0 L of an ideal gas is cooled from $30.0^{\circ} \mathrm{C}$ to $10.0^{\circ} \mathrm{C}$. What happens to the volume? Why? Does anything else change?

Solution The volume remains constant. It's an inflexible steel container. In order for the volume to shrink, you need a collapsible container like a piston and cylinder, or just a water-trapped gas within a glass cylinder. In our steel case, the molecules will slightly slow down, but they will still reach as far as the boundaries of their container. The collisions will be less frequent, and pressure will decrease. So, more specifically, this is actually a Gay Lussac problem, with $P_{1} / T_{1}=P_{2} / T_{2}$. $P_{2}=(10.0+273.15) /(30.0+273.15) P_{1}=0.934 P_{2}$.

Thermochemistry
8. Confusing Enthalpy with Change in Enthalpy

Example: Show the difference on a graph
Solution Enthalpy, H, is the total heat content of a substance, which includes the sum of its potential and kinetic energies. Enthalpy change or $\Delta H$, is the difference in enthalpy between the products and reactants of a physical or chemical reaction.

## 9. Confusing Enthalpy Change with Molar Enthalpy

Example: $\quad$ Given that the reaction $2 \mathrm{~A}+\mathrm{B} \rightarrow \mathrm{A}_{2} \mathrm{~B}+202 \mathrm{~kJ}$, what is the molar enthalpy for A?

Although the molar enthalpy for $B$ or $A_{2} B$ is $\mathbf{- 2 0 2} \mathbf{k J} /$ mole, the molar enthalpy for $A$ is, because of the coefficient in the equation, $-202 \mathrm{~kJ} / 2$ moles = -101 kJ/mole.
10. Inserting the Wrong Mass into $Q=m c \Delta T$ for Neutralization Reactions and Using Wrong $n$

Example: If adding 2.0 g of solid $\mathrm{Ca}(\mathrm{OH})_{2}$ to 100.0 mL of dilute aqueous HCl completely neutralized the acid while causing a $6.6^{\circ} \mathrm{C}$ increase in temperature, what is the molar heat of neutralization of HCl ?

$$
\mathrm{Ca}(\mathrm{OH})_{2(\mathrm{~s})}+2 \mathrm{HCl}_{(\mathrm{aq})} \quad \rightarrow 22 \mathrm{H}_{2} \mathrm{O} \quad+\quad \mathrm{CaCl}_{2}
$$

What goes on in this reaction is that a small amount of base dissolved in relatively lots of water is neutralizing a small amount of acid, which is also dilute. Overall there is a negligible volume change. Basically the mass absorbing the heat $(Q)$ of neutralization is $100.0 \mathbf{~ m l}(1.0 \mathrm{~g} / \mathrm{ml})=100.0$ grams of water, with a specific heat capacity of about $4.19 \mathrm{~J} /\left(\mathrm{g}^{0} \mathrm{C}\right)$, even though there is a bit of salt and water produced almost instantaneously.

Do not use 102.0 g ! The 2.0 g of base is solid in this case.
$Q=m c \Delta T=100.0 \mathrm{~g}\left[4.19 \mathrm{~J} /\left(\mathrm{g}^{\circ} \mathrm{C}\right)\right]\left(6.6^{\circ} \mathrm{C}\right)=2765.4 \mathrm{~J}$
But although the water absorbs the heat, the energy was released by the reaction between hydroxide and $H^{+}$ions, so $\Delta H=-Q=-2765.4 \mathrm{~J}=-2.7654 \mathrm{~kJ}$

How much of this heat is released per mole of HCl that react? Well we need moles of $\mathrm{HCl}=$ twice the moles of calcium hydroxide(see the ratio in the equation). 2 moles $\mathrm{HCl} / \mathrm{mole}$ of $\mathrm{Ca}(\mathrm{OH})_{2}(2.0 \mathrm{~g})\left(\mathrm{mole}\right.$ of $\left.\mathrm{Ca}(\mathrm{OH})_{2} / 74.0 \mathrm{~g}\right)=$ 0.0541 moles $=\mathbf{n}$
$\Delta \mathrm{H} / \mathrm{n}=\mathbf{- 2 . 7 6 5 4 \mathrm { kJ } / 0 . 0 5 4 1 \text { moles } = - 5 1 \mathrm { kJ } / \text { mole of } \mathbf { H C l } , ~}$

Rates
11. Confusing Leftover Moles of a Reactant With the Amount that is Actually Reacting and/or With What is Actually being Produced

Example:
A student was studying the electrolysis of 1 L of $\mathrm{AlCl}_{3(\mathrm{aq)}}$ according to:

Moles of $\mathrm{AlCl}_{3}$ versus time

Using the graph above, calculate the average rate of formation of chlorine gas from 10 s to 20 s .

Construct the following table, noting the ratio from the equation:
$\left.\left.\begin{array}{|c|c|c|c|}\hline \text { Time(seconds) } & \begin{array}{l}\text { Remaining Moles of } \\ \mathrm{AlCl}_{3}\end{array} & \begin{array}{l}\text { Moles of } \mathrm{AlCl}_{3} \text { that } \\ \text { React }\end{array} & \begin{array}{l}\text { Moles of Cl } \\ \mathbf{2}\end{array} \\ \text { Produced }\end{array} \right\rvert\, \begin{array}{|c|c|c|}\hline \mathbf{0} & \mathbf{0 . 5 0} & \mathbf{0 . 5 0 - 0 . 5 0 = 0}\end{array}\right]$

Avg rate $=(0.3495-0.195) /(20-10)=0.015$ moles $\mathrm{Cl}_{2}$ per second.

12 Average Rate: Do not add up and divide by 2. On a curve, rate changes continuously. So to get an approximate average, we find the slope of an imaginary straight line running through the endpoints.

Example: After 2.0 minutes we produced 10 moles of $\mathrm{H}_{2}$. After 8.0 minutes we produced 24 moles. What is the average rate of production of hydrogen gas.

Solution: $\quad \operatorname{avg}$ rate $=\Delta \mathrm{n} / \Delta \mathrm{t}=(24-10)$ moles $/(8.0-2.0$ minutes $)$ $=2.3 \mathrm{moles} / \mathrm{min}$
13. Not Being Able to Identify the Relevant Component of the Fire Triangle

Example: Firemen dig a circular trench around a forest fire. Why?

Solution: This eliminates fuel. There is only dirt in the trench, which unlike grass and trees, is not flammable. Surface area, oxygen and heat are not factors in this case.
14. Not Understanding the Connection between Spontaneity and Rates.

Example: When phosphorus is taken out of oil it spontaneously bursts into flames, forming $\mathrm{P}_{2} \mathrm{O}_{5}$. How and why does this happen? Show a graph with chemical equation.

Solution: It happens because a very small activation energy is needed to burn phosphorous. In other words, the substance formed in between phosphorus and its oxide almost has the same enthalpy as the original, so that phosphorus can absorb the small difference in energy from the colliding air molecules in its environment.

## Equilibrium

15. Incorrect Use of IRFE(ICE) Chart in Calculating K By Ignoring Volume/Stoichiometry

Example: $\quad$ Given: $\quad 2 \mathrm{NO}_{2(\mathrm{~g})}=\mathrm{N}_{2} \mathrm{O}_{4(\mathrm{~g})}$

At a certain temperature 6.0 moles of $\mathrm{NO}_{2}$ and 1.0 moles of $\mathrm{N}_{2} \mathrm{O}_{4(\mathrm{~g})}$ are introduced into a 3.0 L container. At equilibrium we find only 4.0 moles of $\mathrm{NO}_{2}$ along with some $\mathrm{N}_{2} \mathrm{O}_{4}$. Calculate K .

|  | $2 \mathrm{NO}_{2(\mathrm{~g})}=$ | $\mathrm{N}_{2} \mathrm{O}_{4(\mathrm{~g})}$ |
| :--- | :--- | :--- |
| initial | $\mathbf{6 . 0}$ moles | 1.0 moles |
| Changing <br> (reacting/forming) | 6.0 moles $-4.0=2.0$ moles | $\mathbf{2 . 0 / 2 = 1 . 0 \text { moles }}$ |
| equilibrium | 4.0 moles | $\mathbf{1 + 1 = 2 . 0 \text { moles }}$ |

$$
\mathrm{K}=\left[\mathrm{N}_{2} \mathrm{O}_{4(\mathrm{~g})}\right] /\left[\mathrm{NO}_{2(\mathrm{~g})}\right]^{2}=(2.0 / 3.0 \mathrm{~L}) /(4.0 / 3.0 \mathrm{~L})^{2}=0.38
$$

## 16. Assuming that solids and liquids disturb equilibrium

In the same way that we exclude solids and liquids from $\mathrm{K}_{\mathrm{eq}}$ expressions, adding more liquid or solid will not disturb equilibrium.

Look at the diagram below to understand why: The second one has less liquid but there are still two collisions going on (circles are aqueous ions whose concentration will affect equilibrium)

17. Inability to Combine $\mathbf{p H}, \mathrm{pOH}$ concepts with Ka and Kb

Example: What is the Ka of an acid with a pOH of 10.0 if the acid was prepared by dissolving 30.0 g in 2.0 L? Molar mass of $\mathrm{HX}=100.0$.

Solution: $\quad \mathrm{pH}=14.0-\mathrm{pOH}=14.0-10.0=4.0$. This leads to the equilibrium concentration of acid:
$\left[\mathrm{H}^{+}\right]=10-\mathrm{pH}=10^{-4} \mathrm{moles} / \mathrm{L}$
We then run backwards to trace the amount of acid that dissociated in order to get its equilibrium value.

|  | HX | $\mathbf{H}^{+}$ | $\mathbf{X}^{-}$ |
| :---: | :---: | :---: | :---: |
| initial | $\begin{gathered} 30.0 \mathrm{~g} /(100 \mathrm{~g} / \mathrm{mole}) / 2.0 \mathrm{~L}= \\ 0.15 \mathrm{M} \end{gathered}$ | 0 | 0 |
| Changing (reacting/forming) | $10^{-4}$ moles/L | $\begin{aligned} & 10^{-4} \\ & \text { moles/L } \end{aligned}$ | $10^{-4}$ moles/L |
| equilibrium | 0.15-10 ${ }^{-4}$ moles/L | $\begin{aligned} & 10^{-4} \\ & \text { moles/L } \end{aligned}$ | $10^{-4}$ moles/L |
|  |  |  |  |

$\mathrm{Ka}=\left[\mathrm{H}^{+}\right]\left[\mathrm{X}^{-}\right] /[\mathrm{HX}]=\left[10^{-4}\right]\left[10^{-4}\right] /\left[0.15-10^{-4}\right]=6.6 \mathrm{X} \mathrm{10}{ }^{-8}$

## 18. Treating Standard Reduction Potentials like $\Delta H$.

Example: Find the overall voltage for an electrochemical cell consisting of lithium and gold electrodes in standard solutions.

Although the sign of an $E$ value changes when we reverse the reaction, we do not multiply the voltage by the coefficient needed by the chemical reagents.

$$
\begin{array}{lll}
3 \mathrm{Li} \rightarrow 3 \mathrm{Li}^{+}+3 \mathrm{e}^{-} & +3.04 \mathrm{~V} & \begin{array}{l}
\text { (sign was switched : reversed eqn; } \\
\text { factor of } 3 \text { not applied to } E \text { value) }
\end{array} \\
\mathrm{Au}^{+3}+3 \mathrm{e}^{-} \rightarrow \mathrm{Au} & +1.50 \mathrm{~V} &
\end{array}
$$

Sum: $3 \mathrm{Li}+\mathrm{Au}^{+3} \rightarrow 3 \mathrm{Li}^{+}+\mathrm{Au} \quad+4.54 \mathrm{~V}$
